

# Terraform Lab Report: Creating Multiple EC2 Instances with Loops

## Objective

In this lab, I learned how to create multiple EC2 instances dynamically using two types of loops in Terraform:

- count
- for\_each

## Steps I Followed

### Part 1: count

1. Created a folder named terraform-multiple-instances
2. Wrote a main.tf file to create 3 EC2 instances using count = 3
3. Used this AMI ID: ami-03c1aa37835df06a1 (Ubuntu 20.04 in us-east-1)
4. Ran terraform init and then terraform apply -auto-approve
5. Verified the 3 EC2 instances in the AWS Console
6. Destroyed the instances with terraform destroy -auto-approve

## Problems I Faced & How I Solved Them

Problem	Solution
Old AMI ID not found	Searched for the latest AMI on Ubuntu AMI Locator
AMI not valid in the region	Verified region is us-east-1 and matched the AMI
File saved as .tf.txt	Fixed the filename to just main.tf

## Screenshots Taken

- Terraform init output
- Terraform apply output
- AWS Console showing EC2 instances
- Terraform destroy output

Terraform has created a lock file .terraform.lock.hcl to record the provider
selections it made above. Include this file in your version control repository
so that Terraform can guarantee to make the same selections by default when
you run "terraform init" in the future.

Terraform has been successfully initialized!

You may now begin working with Terraform. Try running "terraform plan" to see
any changes that are required for your infrastructure. All Terraform commands
should now work.

If you ever set or change modules or backend configuration for Terraform,
rerun this command to reinitialize your working directory. If you forget, other
commands will detect it and remind you to do so if necessary.
